This Protocol considers this test or procedure investigational. If the physician feels this service is medically necessary, preauthorization is recommended.

The following Protocol contains medical necessity criteria that apply for this service. The criteria are also applicable to services provided in the local Medicare Advantage operating area for those members, unless separate Medicare Advantage criteria are indicated. If the criteria are not met, reimbursement will be denied and the patient cannot be billed. Please note that payment for covered services is subject to eligibility and the limitations noted in the patient’s contract at the time the services are rendered.

Description

Glioblastoma multiforme (GBM) is the most common and deadly malignant brain tumor. It has a very poor prognosis and is associated with low quality of life during the course of treatment. Tumor-treatment fields (TTF) therapy is a new, noninvasive technology that is intended to treat glioblastoma using electric fields.

Summary of Evidence

The evidence for tumor-treatment fields therapy in patients who have recurrent glioblastoma multiforme includes one randomized controlled superiority pivotal trial using the U.S. Food and Drug Administration–approved device and a number of small observational studies. Relevant outcomes include overall survival (OS), quality of life (QOL), and treatment-related morbidity. The pivotal trial had numerous methodologic limitations and failed to demonstrate an improvement in OS or disease response. There were some differences reported in QOL, but these data were limited by a low response rate for QOL measures. In addition, the best standard chemotherapy protocols reported in the randomized controlled trial may not reflect current practice, given the increased use of bevacizumab and temozolomide for treatment of patients with recurrent glioblastoma. No data were available to address a comparison to other treatment modalities (e.g., radiation, surgery, combination therapy). The evidence is insufficient to determine the effects of the technology on health outcomes.

Policy

Tumor-treatment fields therapy to treat glioblastoma is considered investigational.
Medicare Advantage

For Medicare Advantage tumor-treatment fields therapy is considered **not medically necessary**.

**Background**

Glioblastomas, also known as glioblastoma multiforme (GBM), are the most common form of malignant primary brain tumor in adults. They comprise approximately 15% of all brain and central nervous system tumors and more than 50% of all tumors that arise from glial cells. The peak incidence for GBM occurs between the ages of 45 and 70 years. GBMs are grade IV astrocytomas, the most deadly type of glial cell tumor, and are often resistant to standard chemotherapy. According to the National Comprehensive Cancer Network, GBM is the “deadliest brain tumor with only a third of patients surviving for one year and less than 5% living beyond five years.”

The primary treatment for GBM is debulking surgery to remove as much of the tumor as possible. At that time, some patients may undergo implantation of the tumor cavity with a carmustine (bis-chloroethyl)nitrosourea [BCNU]‒impregnated wafer. Depending on the patient’s physical condition, adjuvant radiotherapy, chemotherapy (typically temozolomide), or a combination of the two are sometimes given. After adjuvant therapy, some patients may undergo maintenance therapy with temozolomide.

No standard treatment exists for recurrent GBM. In patients with disease that recurs after these initial therapies, additional debulking surgery may be used if recurrence is localized. Other treatment options for recurrent disease include various forms of systemic medications such as bevacizumab, bevacizumab plus chemotherapy (e.g., irinotecan, BCNU/chloroethyl)nitrosourea [CCNU], temozolomide), temozolomide, nitrosourea, PCV (procarbazine, CCNU, vincristine), cyclophosphamide, and platinum-based agents. External beam radiotherapy (EBRT) also may be used to treat recurrent GBM. Response rates in recurrent disease are less than 10%, and progression-free survival rates at six months are less than 20%.

TTF therapy is a new, noninvasive technology that is intended to treat GBM on an outpatient basis using electrical fields. TTF therapy exposes cancer cells to alternating electric fields of low intensity and intermediate frequency, which are purported to both selectively inhibit tumor growth and reduce tumor angiogenesis. TTF are proposed to inhibit rapidly dividing tumor cells by two mechanisms, arrest of cell proliferation and destruction of cells while undergoing division.

The NovoTTF-100A™ System (Novocure, Haifa, Israel) has received FDA marketing approval to deliver TTF therapy. TTF therapy via the NovoTTF-100A™ System is delivered by a battery-powered, portable device that generates the fields via disposable electrodes that are noninvasively attached to the patient’s shaved scalp over the site of the tumor. The device is used by the patient at home on a continuous basis (20-24 h/d) for the duration of treatment, which can last for several months. Patients can carry the device in a backpack or shoulder pack while carrying out activities of daily living.

**Regulatory Status**

The NovoTTF-100A™ System (assigned the generic name of TTF) was approved by FDA in April 2011 through the premarket approval process. The FDA-approved label reads as follows: “The NovoTTF-100A System is intended as a treatment for adult patients (22 years of age or older) with confirmed GBM, following confirmed recurrence in an upper region of the brain (supratentorial) after receiving chemotherapy. The device is intended to be used as a stand-alone treatment, and is intended as an alternative to standard medical therapy for recurrent GBM after surgical and radiation options have been exhausted.”

On September 28, 2014, FDA approved a request for Novocure to change its products name from NovoTTF-110A System to Optune™.
On May 11, 2015, FDA granted a priority review status for Novocure’s premarket approval supplemental applications for the use of Optune in combination with temozolomide for newly diagnosed glioblastoma. Product code: NZK.
